

FC Highbury — BI & CRM Consulting Project

Individual Contribution — Subhash Lora Jat

MSc Data Analytics, National College of Ireland | Business Intelligence & Business Analytics | Group project, 3 members (~33% individual share)

FC Highbury is a fictional football club case study used to design and implement a business-intelligence and CRM solution addressing untracked fan data, low commercial revenue share, and no operational visibility. My share of the group deliverable covered the CRM build, one of three Power BI dashboards, and a comparative analysis of AI-generated BI against the team's manual dashboards.

SALESFORCE CRM IMPLEMENTATION

- Designed 4 custom objects (Region, Member, Matchday Hospitality Booking, Ticket) with lookup relationships enforcing one-region-per-member and one-to-many bookings/tickets.
- Built validation rules for data integrity: guest-count bounds, no confirming past-dated matches, no future birth/join dates.
- Automated two Salesforce Flows — booking-confirmed status updates, and a High-Value Booking Alert that posts to Chatter and creates a follow-up task above a value threshold.
- Combined 3 summary reports (Bookings by Package Tier, Members by Region, SLA Compliance) into one operational dashboard.
- **Result:** SLA compliance rose from 33% to 100% (3/9 → 9/9 tickets on time), average resolution time fell from 27.1 to 8.6 hours.

FANS & OPERATIONS POWER BI DASHBOARD

- Built the operating-spend breakdown by category, identifying electricity, scouting fees, and stadium rent/lease as the largest cost lines to support a supplier-diversification recommendation.
- Analysed merchandise profit by acquisition channel, country, loyalty tier and category — found kits/footwear drive ~78% of merchandise profit and Asia-Pacific/Americas together contribute ~53%, an underexploited market.

AI-GENERATED DASHBOARD — COMPARATIVE ANALYSIS

- Built a fourth dashboard using an AI tool over the same combined dataset and benchmarked it against the three manually-built dashboards.
- Verified the AI dashboard reproduced the CRM's SLA figures independently from raw ticket data, confirming genuine data aggregation rather than fabrication.
- Identified that the AI dashboard surfaced a real insight the manual dashboards missed — net income falling every season since 2023/24, turning negative in 2025/26 — invisible in the manual work because it was split across three non-cross-referenced files.
- Concluded AI tooling is faster at cross-dataset synthesis but manual builds retain data-quality control the AI lacked; recommended using both together.

DATA QUALITY FIXES

- Corrected an Injury Risk Score calculation where positional injury-frequency values (actual range 1.5–4.0) were being used as if scaled 0–1, which would have flagged every player high-risk; fixed with min–max normalisation.
- Cleaned inconsistent position labels, text-encoded substitute ratings, and open injuries recorded as placeholder text instead of null dates.
- Found and removed a duplicate CRM Region record and fixed an invalid merge-field token in the High-Value Booking Alert flow during testing.
